

Security risk assessment report

Part 1: Select up to three hardening tools and methods to implement

Patch updates

Multifactor authentication (MFA)

Disabling unused ports

Part 2: Explain your recommendations

Patch updates: Keeps systems protected against known vulnerabilities. Attackers often exploit unpatched software first. Regular updates drastically reduce exposure.

MFA: Adds a strong layer of identity verification, preventing unauthorized access even if passwords are compromised.

Disabling unused ports: Closes potential entry points for attackers, reducing the network's attack surface and preventing exploitation of unnecessary services.
